Abstract

In a recent paper Auffinger, Ben Arous and Černý gave an asymptotic evaluation of the complexity of spherical p -spin spinglass models via random matrix theory. This yields an interesting layered structure of the low critical values for the Hamiltonian of these models. This bachelor thesis aims to provide an overview of some techniques needed to prove and thoroughly understand the above mentioned results.

In particular, results of independent interest include Wigner's semicircle law and various large deviation principles.

Introduction

Since spherical spin glasses can be seen to be a reasonable mathematical model for a lot of applications in statistics (e.g. neural networks, financial mathematics) and physics it is of great interest to investigate the distribution of critical points.

0.1 Notations

Let $S^{N-1}(r) \subseteq \mathbb{R}^N$ denote the Euclidean sphere of radius r and fix p to be an integer larger or equal to 2. Now consider the Hamiltonian of p -spherical spin glasses $H_{N,p} : S^{N-1}(\sqrt{N}) \rightarrow \mathbb{R}$, given by

$$H_{N,p}(\boldsymbol{\sigma}) = \frac{1}{N^{(p-1)/2}} \sum_{i_1, \dots, i_p=1}^N J_{i_1, \dots, i_p} \sigma_{i_1} \dots \sigma_{i_p},$$

where the J_{i_1, \dots, i_p} are independent centered standard Gaussian random variables and $\boldsymbol{\sigma} = (\sigma_1, \dots, \sigma_N)$ referred to as states.

For any Borel set $B \subset \mathbb{R}$ we introduce the (random) number of critical points $Crt_{N,k}(B)$ with index k , defined as

$$Crt_{N,k}(B) = \sum_{\boldsymbol{\sigma} : \nabla H_{N,p}(\boldsymbol{\sigma})=0} \mathbf{1}\{H_{N,p}(\boldsymbol{\sigma}) \in NB\} \mathbf{1}\{i(\nabla^2 H_{N,p}(\boldsymbol{\sigma})) = k\},$$

where $i(\cdot)$ is the index function, i.e. it counts the number of negative eigenvalues of its argument, and NB is defined as $\{Nx : x \in B\}$. Furthermore, let $Crt_N(B) := \sum_k Crt_{N,k}(B)$ be the number of critical points regardless of their index. By abuse of notation, let $Crt_N(u) = Crt_N((-\infty, Nu])$ for all $u \in \mathbb{R}$.

0.2 Main Results

The distribution of critical points with given index of some function $f : K \rightarrow \mathbb{R}$ is of interest since, roughly speaking, it encodes the topology of the “landscape” induced by f , i.e. its graph $\{(x, f(x)) \in K \times \mathbb{R} : x \in K\}$. This is beyond the scope of this thesis, but it is done rigorously in the field of Morse theory. Instead we will focus on getting a better understanding of the distribution of the critical points of the Hamiltonian $H_{N,p}$, for some fixed p , on an exponential scale, asymptotically as N goes to infinity, by obtaining a large deviation principle for their first moments. Higher moment calculations have been done recently in Subag and Zeitouni (2015).

Intuitively this means that we calculate $\mathbb{E}[Crt_{N,k}]$ up to some subexponential, additive factor for very large systems.

Theorem 0.2.1. *[Large deviations for $\mathbb{E}[Crt_{N,k}(u)]$]*

$$\lim_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}[Crt_{N,k}(u)] = \Theta_{k,p}(u) \quad (1)$$

and

$$\lim_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}[Crt_N(u)] = \Theta_p(u), \quad (2)$$

for

$$\Theta_p(u) = \begin{cases} \frac{1}{2} \log(p-1) - \frac{p-2}{4(p-1)} u^2 - I_1(u), & \text{if } u \leq -E_\infty \\ \frac{1}{2} \log(p-1) - \frac{p-2}{4(p-1)} u^2, & \text{if } -E_\infty \leq u \leq 0 \\ \frac{1}{2} \log(p-1), & \text{if } 0 \leq u \end{cases}$$

and

$$\Theta_{k,p}(u) = \begin{cases} \frac{1}{2} \log(p-1) - \frac{p-2}{4(p-1)} u^2 - (k+1)I_1(u), & \text{if } u \leq -E_\infty \\ \frac{1}{2} \log(p-1) - \frac{p-2}{4(p-1)} u^2, & \text{if } u \geq E_\infty \end{cases},$$

where $E_\infty = E_\infty(p) = 2\sqrt{\frac{p-1}{p}}$ and $I_1 : (-\infty, E_\infty] \rightarrow \mathbb{R}$ is given by

$$I_1(u) = \frac{2}{E_\infty^2} \int_u^{-E_\infty} \sqrt{z^2 - E_\infty^2} dz.$$

One particularly interesting consequence of this result is that $H_{N,p}$ exhibits a “layered structure” in the sense that, on an exponential scale, “most” critical points σ with higher index $i(\nabla^2 H_{N,p}(\sigma))$ correspond to higher energy levels $H_{N,p}(\sigma)$. This statement is made precise with the following theorem:

Theorem 0.2.2 (Layered structure). *For all $k \geq 0$ and $\varepsilon > 0$ we have*

$$\limsup_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{P} \left(\left\{ \sum_{i=k}^{\infty} \text{Crt}_{N,i}(-E_k - \varepsilon) > 0 \right\} \right) < 0, \quad (3)$$

where $E_k = E_k(p)$ is the unique solution to $\Theta_{k,p}(-E_k) = 0$.

0.3 Outline

The intuition is that we would to use a probabilistic generalisation of the Kac-Rice formula on the derivative of the Hamiltonian to get an analytic expression for the expected number of critical points in some region which will then be simplified to the problem of counting eigenvalues of some “GOE-like” object.

To make this precise we need to know about the covariance structure of the GOE, how moments behave under conditioning and a large deviation principle for the k -th largest eigenvalue of the GOE.

Finally, one can use Varadhan’s lemma and Wigner’s semicircle law to arrive at the main results stated above.

0.4 Gaussian Orthogonal Ensemble

Definition 0.1. *The Gaussian Orthogonal Ensemble (henceforth referred to as GOE) is an ensemble of symmetric $N \times N$ matrices $H = H_N$ with centered Gaussian entries H_{ij} , normalized in the following way: $\mathbb{E}H_{ij}^2 = 1 + \delta_{ij}$.*

Remark (Density in the space of matrices). *Their density is given by the Gaussian measure*

$$d\mathbb{P}(H) = Z_N^{-1} \exp \left(-N \frac{1}{4} \text{tr} H^2 \right) \quad (4)$$

with normalization constant $Z_N = \int d\mathbb{P}(H) \prod_{1 \leq i \leq j \leq N} dH_{ij}$ which is a shorter way of writing $Z_N^{-1} \exp \left\{ -N \frac{1}{4} \left(2 \sum_{i < j}^N H_{ij}^2 + \sum_{i=j}^N H_{ij}^2 \right) \right\}^1$

Theorem 0.4.1 (Joint probability density of eigenvalues). *The joint probability density Q_N of the unordered eigenvalues $\{\lambda_i\}_{i=1}^N$ of the GOE is given by*

$$Q_N(d\lambda_1, \dots, d\lambda_N) = C_N \prod_{i < j} |\lambda_i - \lambda_j| \prod_i \exp(-N\lambda_i^2/4) d\lambda_i,$$

¹Note that $\text{tr} H^2 = \sum_i [H^2]_{ii}$ and $[H^2]_{ii} = \sum_j H_{ij} H_{ji} = \sum_j |H_{ij}|^2$ by hermiticity.

for some $C_N > 0$ which is uniquely determined for normalization.

Proof. We follow Liu (2000). Let H be some element of the GOE. Since it is symmetric there is a decomposition in $H = UDU^T$ with U orthogonal and $D = \text{diag}(\lambda_1, \dots, \lambda_N)$. Thus we can write

$$H_{ij} = \sum_k \lambda_k U_{ik} U_{jk}. \quad (5)$$

Using the orthogonality of U , $\sum_k U_{ki} U_{kj} = \delta_{ij}$, one can infer that $\sum_{i,j} H_{ij}^2 = \sum_i \lambda_i^2$.

The key idea is to make use of the change of variables formula to go from $\mathbb{P}(\lambda_1, \dots, \lambda_N, \alpha_1, \dots, \alpha_{N(N-1)/2})$ to $\mathbb{P}(H)$. One should think of the $\{\alpha_i\}_{i=1}^{N(N-1)/2}$ as the parameters that determine the matrix U , which, together with the eigenvalues, uniquely determines H .

To do that we first need some information on the determinant of the Jacobian J of the change of variables: From equation (5) we see the linearity of H_{ij} in the eigenvalues λ_k which implies that $\partial H_{ij} / \partial \alpha$ is linear in the eigenvalues². Hence, $\det J$ has to be a polynomial of degree $N(N-1)/2$ in the eigenvalues. If two eigenvalues coincide U cannot be uniquely determined anymore and thus the inverse of the transformation is not unique, meaning that $\det J = 0$. So the determinant of the Jacobian must vanish for all $\lambda_i = \lambda_j, i \neq j$, which is achieved if it contains a factor $\lambda_i - \lambda_j$. However, there are exactly $N(N-1)/2$ such factors and since that is just the degree of the polynomial it follows that we have completely accounted for J 's dependence on the eigenvalues by writing

$$\det J = \prod_{i < j} (\lambda_i - \lambda_j) h(\alpha_1, \dots, \alpha_{N(N-1)/2}).$$

Now we can write

$$\begin{aligned} & \mathbb{P}(\lambda_1, \dots, \lambda_N, \alpha_1, \dots, \alpha_{N(N-1)/2}) = \\ & \mathbb{P}(H) |\det J| = Z_N^{-1} \exp \left(-N \frac{1}{4} \sum_i \lambda_i^2 \right) \left| \prod_{i < j} (\lambda_i - \lambda_j) h(\alpha_1, \dots, \alpha_{N(N-1)/2}) \right|. \end{aligned}$$

Integrating out the dependence on $\{\alpha_k\}_{k=1}^{N(N-1)/2}$ yields the desired result. \square

²To be precise, it is linear in the *vector*.

0.5 Wigner's Semicircle Law

This section will follow Tao (2010) quite closely while trying to be as self-contained as possible.

Definition 0.2 (Wigner matrix). *A Wigner matrix M is a complex, Hermitian matrix with independent and identically distributed entries M_{ij} for $i \geq j$ and with mean 0 and variance 1 for $i > j$. The diagonal entries M_{ii} have bounded mean and variance.*

If M_n is an n -dimensional Wigner matrix it can be shown that the operator norm $\|M_n\|_{OP}$ is typically of size $O(\sqrt{n})$, so it is natural to define the empirical spectral distribution (ESD) of any Hermitian matrix M_n as follows:

Definition 0.3 (ESD).

$$\mu_{M_n} := \frac{1}{n} \sum_{j=1}^n \delta_{\lambda_j(M_n)},$$

where $\lambda_1(M_n) \leq \dots \leq \lambda_n(M_n)$ are the ordered, real eigenvalues of M_n .

Since we are considering random matrices the ESDs will be random as well and thus it is interesting to ask if there is a measure on the real line μ such that it is the weak limit $\mu_{M_n/\sqrt{n}} \rightharpoonup \mu$ of $\mu_{M_n/\sqrt{n}}$, that is $\int_{\mathbb{R}} \varphi d\mu_{M_n/\sqrt{n}}$ converges in almost surely against $\int_{\mathbb{R}} \varphi d\mu$ for all bounded³ and continuous φ . This can also be derived from the more general definition of convergence in probability or almost sure convergence, but we will not do that here.

Surprisingly such a limit μ exists and is even deterministic.

Theorem 0.5.1 (Wigner's semicircle law). *Let M_n be the top left $n \times n$ minors of an infinite Wigner matrix, then the ESDs $\mu_{M_n/\sqrt{n}}$ converge weakly in probability⁴ to the Wigner semicircle distribution given by*

$$\mu_{sc} := \begin{cases} \frac{1}{2\pi} \sqrt{4 - |x|^2} dx, & \text{if } |x| \leq 2 \\ 0, & \text{else} \end{cases} =: \frac{1}{2\pi} \sqrt{4 - x^2}_+ dx.$$

A rough outline of the proof is given by this list of intermediary results that will be shown:

³Thanks to the concentration of measure results to be shown later we only have to check it for $\varphi \in C_c(\mathbb{R})$.

⁴Even almost sure convergence can be shown, but we will not do so in this proof.

1. Show that without loss of generality we can set the diagonal elements to zero and bound all other entries by some constant. Additionally some classic concentration of measure results will be shown.
2. To show that $\mu_n \rightarrow \mu$ almost surely, it suffices to show that the respective Stieltjes transforms converge almost surely, pointwise in the upper half plane, i.e. $\mu_n \rightarrow \mu \Leftrightarrow \forall z \in \mathbb{C} : \text{Im}(z) > 0 : s_{\mu_n}(z) \rightarrow s_\mu(z)$ almost surely.
3. The Stieltjes transform $s_n := s_{\mu_{M_n/\sqrt{n}}}$ is “stable in n ”, i.e. $s_n(z) = s_{n-1}(z) + O(\frac{1}{n})$, where O can depend on z and even $s_n(z) - \mathbb{E}s_n(z) \rightarrow 0$ almost surely.
4. Derive the semicircle law by deriving the recursion $\mathbb{E}s_n(z) = -\frac{1}{z + \mathbb{E}s_n(z)} + o(1)$, where, again, $o(1)$ will depend on z and “inverting” the Stieltjes transform.

Remark. Note that instead of step 4 one could have plugged in the semicircle distribution and simplified the proof by just checking that this is indeed the limit. This is not done here because we want to see how the Stieltjes transform method can be used to derive such a conclusion without knowing about it beforehand.

Also, there are other proofs (e.g. Boutet de Monvel and Khorunzhiy (2015)) specifically for the GOE/GUE (instead of the more general Wigner matrices) which exploit their symmetries to shorten the proof considerably.

0.5.1 Preliminary Reductions

Lemma 0.5.2. For the matrices M_n as given in 0.5.1 it can be assumed without loss of generality that the diagonal entries are zero and the absolute values $|[M_n]_{ij}|$ are bounded by some constant $C > 0$ which does not depend on i, j or n .

Proof. For every n define the normalized random variables $X_n = M_n/\sqrt{n}$ and \bar{X}_n by setting the diagonal elements to zero, bounding every entry and recentering it accordingly, i.e.

$$[\bar{X}_n]_{ij} := \begin{cases} [X_n]_{ij} \mathbf{1}_{|[M_n]_{ij}| \leq C} - \mathbb{E} \left[[X_n]_{ij} \mathbf{1}_{|[M_n]_{ij}| \leq C} \right], & \text{if } i \neq j \\ 0, & \text{if } i = j \end{cases}.$$

Now we want to show that convergence of the ESD $\mu_{\bar{X}_n}$ to μ implies convergence of μ_{X_n} to the same limit μ . To do so it suffices to show that

$|\int \varphi d\mu_{X_n} - \int \varphi d\mu_{\bar{X}_n}| \rightarrow 0$ for every smooth φ with compact support. In particular every such φ is a Lipschitz function with Lipschitz-constant $\|\varphi'\|_{L^\infty}$. By denoting the eigenvalues of X_n, \bar{X}_n as $\lambda_i, \bar{\lambda}_i$ and invoking the Weilandt-Hoffmann inequality (0.5.4) we get the following bound:

$$\begin{aligned} \left| \int \varphi d\mu_{X_n} - \int \varphi d\mu_{\bar{X}_n} \right| &\leq \|\varphi'\|_{L^\infty} \frac{1}{n} \sum_{i=1}^n |\lambda_i - \bar{\lambda}_i| \leq \\ &\|\varphi'\|_{L^\infty} \left[\frac{1}{n} \sum_{i=1}^n |\lambda_i - \bar{\lambda}_i|^2 \right]^{1/2} \leq \|\varphi'\|_{L^\infty} \left[\frac{1}{n} \text{tr}((X_n - \bar{X}_n)^2) \right]^{1/2}. \end{aligned}$$

Now we need to show that for every $\varepsilon, \delta > 0$ we can find a C such that $\mathbb{P}\left(\frac{1}{n} \text{tr}((X_n - \bar{X}_n)^2) > \varepsilon\right) < \delta$ for large enough n .

Using the definitions one sees that

$$\frac{1}{n} \text{tr}((X_n - \bar{X}_n)^2) \leq \frac{1}{n^2} \sum_{i \neq j} [Y_n]_{ij}^2 + \frac{1}{n} \sum_i [X_n]_{ii}^2,$$

where $Y_n = [M_n]_{ij} \mathbf{1}_{|[M_n]_{ij}| \leq C} - \mathbb{E} \left[[M_n]_{ij} \mathbf{1}_{|[M_n]_{ij}| \leq C} \right]$ and the second term vanishes almost surely as $n \rightarrow \infty$ according to the strong law of large numbers (and the fact that $|X_n|$ vanishes in the limit). So we can use this to bound the probability of the event $\frac{1}{n} \text{tr}((X_n - \bar{X}_n)^2) > \varepsilon$ by

$$\mathbb{P} \left(\left| \frac{1}{n} \text{tr}((X_n - \bar{X}_n)^2) \right| > \varepsilon \right) \leq \frac{1}{n^2} \sum_{i \neq j} \mathbb{P}([Y_n]_{ij}^2 > \varepsilon).$$

To see that this goes to zero for large C we apply Markov's inequality, yielding

$$\begin{aligned} \mathbb{P}(|[Y_n]_{ij}^2| > \varepsilon) &\leq \frac{1}{\varepsilon} \mathbb{E} [|Y_n]_{ij}^2] \leq \\ &\frac{1}{\varepsilon} \left(\mathbb{E} [[M_n]_{ij}^2 \mathbf{1}_{|[M_n]_{ij}| > C}] + \mathbb{E} [[M_n]_{ij} \mathbf{1}_{|[M_n]_{ij}| > C}]^2 \right). \end{aligned}$$

Since the entries $[M_n]_{ij}$ have finite variance (uniformly in n) the right hand side will go to zero as $C \rightarrow \infty$ which proves the claim. \square

Theorem 0.5.3 (Talagrand's concentration inequality). *Let $K > 0$ and X_1, \dots, X_n be independent complex variables with $|X_i| < K$ for all $1 \leq i \leq n$.*

n. Identifying \mathbb{C} with \mathbb{R}^2 , let $F : \mathbb{C}^n \rightarrow \mathbb{R}$ a 1-Lipschitz, convex function. Then for every $\lambda > 0$ one has

$$\mathbb{P}(|F(X) - MF(X)| \geq \lambda K) \leq C \exp^{-c\lambda^2}$$

and

$$\mathbb{P}(|F(X) - \mathbb{E}F(X)| \geq \lambda K) \leq C \exp^{-c\lambda^2}$$

for some absolute constants $c, C > 0$, where $MF(X)$ is the median of $F(X)$.

For the proof refer to <https://terrytao.wordpress.com/2010/01/03/254a-notes-1-concentration-of-measure/#boof0>.

Theorem 0.5.4 (Weilandt-Hoffmann inequality). *For Hermitian⁵ A, B , where $\|B\|_F^2 := \text{tr}(B^2)^{\frac{1}{2}}$ is the Frobenius norm, we have*

$$\sum_{j=1}^n |\lambda_j(A+B) - \lambda_j(A)|^2 \leq \|B\|_F^2.$$

Proof. We fix B to be $B - A$ and show the equivalent statement

$$\sum_{i=1}^n |\lambda_i(A) - \lambda_i(B)|^2 \leq \text{tr}((A - B)^2)$$

and denote by D_M the diagonal matrix $\text{diag}(\lambda_1(M), \dots, \lambda_n(M))$ and U the matrix that diagonalises $B = UD_BU^*$ in the basis of A , such that $\text{tr}(AB) = \text{tr}(D_AUD_BU^*) = \sum_{i,j} \lambda_i(A)\lambda_j(B)|[U]_{ij}|^2$.

Now we have to get some bounds on the “worst case” scenario, that is when $\text{tr}(AB)$ is big. To do so we define $v_{ij} := |[U]_{ij}|^2$ and notice that the above $\text{tr}(AB)$ is linear in v_{ij} . Due to the orthogonality of U one has $\sum_i v_{ij} = \sum_j v_{ij} = 1$ so we can bound $\text{tr}(AB)$ from above by $\sup_{v_{ij} \geq 0, \sum_i v_{ij} = \sum_j v_{ij} = 1} \sum_{i,j} \lambda_i(A)\lambda_j(B)v_{ij}$.

This is an optimization problem of a linear functional over a convex set of doubly stochastic matrices. Hence the maximum is attained at the extreme points which are exactly the permutations. Of all the permutations the identity⁶ gives the maximal value which, after writing out the first inequality proves the theorem. \square

⁵The original Weilandt-Hoffmann inequality holds for normal operators, but we will restrict ourselves to Hermitian ones for simplicity’s sake here.

⁶Writing $x = (\lambda_i(A))_i, y = (\lambda_i(B))_i$, we want to maximize $\langle x, y \rangle$ which, after expanding $\langle x - y, x - y \rangle$, can be seen to be maximized iff $\|x - y\|$ is minimized. In the class of permutations this is achieved by the identity if the eigenvalues are ordered.

Theorem 0.5.5 (Chernoff inequality). *Let X_1, \dots, X_n be independent scalar random variables with $|X_i| \leq K$ almost surely, mean μ_i and variance σ_i^2 . Then for any $\lambda > 0$ there are absolute constants $c, C > 0$ such that*

$$\mathbb{P}(|S_n - \lambda| \geq \lambda\sigma) \leq C \max(e^{-c\lambda^2}, e^{-c\lambda\sigma/K}),$$

where $\lambda := \sum_i \lambda_i$ and $\sigma^2 := \sum_i \sigma_i^2$.

Proof. We begin with some preliminary reductions, namely that it is sufficient to assume X_i to be real valued by taking real and imaginary parts. Furthermore without loss of generality we set $K = 1$ by dividing X_i through K , center X_i (i.e. set μ_i to zero by subtracting its mean), and, by symmetry, only show the upper tail estimate $\mathbb{P}(S_n \geq \lambda\sigma) \leq C \max(e^{-c\lambda^2}, e^{-c\lambda\sigma})$ (with different constants c, C).

To do so we compute the exponential moments $\mathbb{E} \exp(tS_n)$ for some $0 \leq t \leq 1$. By independence of the X_i we have $\mathbb{E} \exp(tS_n) = \prod_{i=1}^n \mathbb{E} \exp(tX_i)$. The $\exp(tX_i)$ can be expanded into a Taylor series $1 + tX_i + O(t^2 X_i^2 \exp(O(t)))$ which, after taking expectation and noting that $|X_i| \leq 1$, yields

$$\mathbb{E} \exp(tX_i) = 1 + O(t^2 \sigma_i^2 \exp(O(t))) = \exp(O(t^2 \sigma_i^2))$$

and hence $\mathbb{E} \exp(tS_n) = \exp(O(t^2 \sigma^2))$. By Markov's inequality we conclude with

$$\mathbb{P}(S_n \geq \lambda\sigma) \leq \exp(O(t^2 \sigma^2) - t\lambda\sigma),$$

which proves the claim after minimising the right hand side in $t \in [0, 1]$. \square

Theorem 0.5.6 (McDiarmid's inequality). *Let X_1, \dots, X_n be independent random variables taking values in ranges R_1, \dots, R_n and let $F : R_1 \times \dots \times R_n \rightarrow \mathbb{C}$, such that for every $1 \leq i \leq n$ we have $|F(x_1, \dots, x_i, \dots, x_n) - F(x_1, \dots, x'_i, \dots, x_n)| \leq c_i$. Then for any $\lambda > 0$ one has*

$$\mathbb{P}(|F(X) - \mathbb{E}F(X)| > \lambda\sigma) \leq C \exp^{-c\lambda^2},$$

for some absolute⁷ constants $c, C > 0$ and $\sigma = \sum_{i=1}^n c_i^2$.

Proof. Similar as above we may assume that F is real, it suffices to show the upper tail estimate $\mathbb{P}(F(X) - \mathbb{E}F(X) \geq \lambda\sigma^2) \leq C e^{-c\lambda^2}$ and try to bound the exponential moment $\mathbb{E} e^{tF(X)}$.

⁷Constants that maintain the same value wherever they occur. In particular applying McDiarmid's inequality in different settings we do not need to consider C_n, c_n , but can still write C, c .

To get a better idea how the exponential moment behaves we write it in such a way that we can use the fact that F does not fluctuate “too much”, i.e. we consider the conditional expectation $\mathbb{E}(e^{tF(X)}|X_1, \dots, X_{n-1})$ for X_1, \dots, X_{n-1} fixed and write this as

$$\mathbb{E}(e^{tF(X)}|X_1, \dots, X_{n-1}) = \mathbb{E}(e^{tY}|X_1, \dots, X_{n-1})e^{t\mathbb{E}(F(X)|X_1, \dots, X_{n-1})},$$

where $Y := F(X) - \mathbb{E}(F(X)|X_1, \dots, X_{n-1})$.

Now we want to control the first term on the right hand side. Since tY has mean zero and variance $t^2 c_n^2$ we can (just in the proof of Chernoff’s inequality) expand to get a Taylor series and take expectations to get

$$\mathbb{E}(e^{tY}|X_1, \dots, X_{n-1}) \leq e^{O(t^2 c_n^2)}.$$

Integrating out the conditioning (note that X_i are independent) we get the following bound on the exponential moment

$$\mathbb{E}e^{tF(X)} \leq e^{O(t^2 c_n^2)} \mathbb{E}e^{t\mathbb{E}(F(X)|X_1, \dots, X_{n-1})}.$$

Basically we reduced the problem by one dimension and noting that $\mathbb{E}(F(X)|X_1, \dots, X_{n-1})$ is a function $F_{n-1}(X_1, \dots, X_{n-1})$ with the same properties as in the theorem’s assumptions on F the above calculations can be performed iteratively n times to get the upper bound

$$\mathbb{E}e^{tF(X)} \leq \exp\left(\sum_{i=1}^n O(t^2 c_i^2) + t\mathbb{E}F(X)\right).$$

Dividing by $\exp(t\mathbb{E}F(X))$ and applying Markov’s inequality yields

$$\mathbb{P}(F(X) - \mathbb{E}F(X) \geq \lambda\sigma) \leq \exp(O(t^2\sigma^2) - t\lambda\sigma),$$

which, after minimising the right hand side in $0 \leq t \leq 1$, proves the claim. \square

0.5.2 Stieltjes Transform

Definition 0.4 (Stieltjes transform). *For a probability measure μ we write s_μ for its Stieltjes transform*

$$\int_{\mathbb{R}} \frac{1}{x - z} d\mu(x).$$

As mentioned above, s_n will be a shorthand for $s_{\mu_{M_n/\sqrt{n}}}$.

Lemma 0.5.7 (Properties of the Stieltjes transform). *In the following let μ be some probability measure.*

1. For $z = a + ib$ we have $\operatorname{Im} \frac{1}{x-z} = \frac{b}{(x-a)^2 + b^2} > 0$.
2. s_μ is analytic in $\mathbb{C} \setminus \operatorname{supp}(\mu) \supset \mathbb{C}_+$.
3. We can bound the absolute value as well as the derivatives by $|\frac{d^j}{dz^j} s_\mu(z)| \leq O(|\operatorname{Im}(z)|^{-(j+1)})$ for all $j \in \{0, 1, \dots\}$.

Proof. The first property is trivial, the second one can be seen by integrating s_μ over any contour not containing the support of μ , interchanging the order of integration and noting that integrating $\frac{1}{x-z}$ gives 0 by Cauchy's integral formula ($\frac{1}{x-z}$ being holomorphic outside the support of μ). The Stieltjes transform being holomorphic (and thus analytic) follows by Morera's theorem.

The third property can be obtained by using $\frac{1}{x-z} \leq \frac{1}{\operatorname{Im}(z)}$ and using Cauchy's integral formula integrating this inequality. \square

Corollary 0.5.7.1. *From lemma 0.5.7, 1 it follows that s_μ is a Herglotz function and thus (e.g. Teschl (2009)) $\operatorname{Im}(s_\mu(\cdot + ib)) \rightarrow \pi\mu$ as $b \rightarrow 0^+$ in the vague topology or equivalently (by $s_\mu(z) = s_\mu(\bar{z})$)*

$$\frac{s_\mu(\cdot + ib) - s_\mu(\cdot - ib)}{2\pi i} \rightarrow \mu. \quad (6)$$

*Note that this can also be seen by writing $\operatorname{Im}(s_\mu)$ as the convolution $\pi\mu * P_b(a)$ with the Poisson kernels $P_b(x) := \frac{1}{\pi} \frac{b}{x^2 + b^2} = \frac{1}{b} P_1(\frac{x}{b})$ which form a family of approximations to the identity.*

Theorem 0.5.8 (Stieltjes continuity theorem). *For μ_n (realisations of) random measures and μ a deterministic measure the following statement holds:*

μ_n converges against μ almost surely in the vague topology if and only if $s_{\mu_n}(z) \rightarrow s_\mu(z)$ almost surely for every $z \in \mathbb{C}_+$.

Proof. “ \Rightarrow ”: If μ_n almost surely converges against a deterministic limit μ in the vague topology, then $\forall \phi \in C_c(\mathbb{R}) : \lim_{n \rightarrow \infty} \int_{\mathbb{R}} \phi d\mu_n = \int_{\mathbb{R}} \phi d\mu$ by definition and, by taking the completion, for all bounded, continuous functions vanishing at infinity. The function $x \mapsto \frac{1}{x-z}$ for some $z \in \mathbb{C}$ with

$Im(z) > 0$ is bounded and continuous on \mathbb{R} and hence $s_{\mu_n}(z) \rightarrow s_{\mu}(z)$ almost surely.

“ \Leftarrow ”: One can, up to an arbitrary small error $\varepsilon > 0$, approximate $\int_{\mathbb{R}} \phi d\mu$ by $\int_{\mathbb{R}} \phi * P_b d\mu = \frac{1}{\pi} \int_{\mathbb{R}} \phi(a) s_{\mu}(a + ib) da$ (and analogously for μ_n). Thus we have $\frac{1}{\pi} \int_{\mathbb{R}} \phi(a) (s_{\mu}(a + ib) - s_{\mu_n}(a + ib)) da$ being equal to the difference (we are interested in) $\int_{\mathbb{R}} \phi d\mu - \int_{\mathbb{R}} \phi d\mu_n$ up to an error ε and by dominated convergence (the Stieltjes transform of a measure is bounded for every $z \in \mathbb{C}_+$ and vanishes outside some compact set) we have convergence in the vague topology. \square

0.5.3 Stableness and Concentration of Measure

In the following we keep using the notation as defined in 0.5.1. To show that $s_n(z) = s_{n-1}(z) + O_z(1/n)$ we first need to prove the following theorem:

Theorem 0.5.9 (Cauchy’s interlacing theorem). *For any $n \times n$ Hermitian matrix A_n with top left minor A_{n-1} and eigenvalues of descending order ($\lambda_i \geq \lambda_{i+1}$) we have:*

$$\lambda_{i+1}(A_n) \leq \lambda_i(A_{n-1}) \leq \lambda_i(A_n),$$

for all $1 \leq i < n$.

Proof. Using the min-max/max-min theorems

$$(\lambda_i(A) = \inf_{\dim(V)=n-i+1} \sup_{v \in V: \|v\|=1} \langle Av, v \rangle \text{ and}$$

$$\lambda_i(A) = \sup_{\dim(V)=i} \inf_{v \in V: \|v\|=1} \langle Av, v \rangle \text{ respectively, c.f. Teschl (2009) p.141)}$$

and writing S_{n-i+1} for $\{v \in \text{span}\{a_i, \dots, a_n\} : \|v\| = 1\}$, where $A_{n-1}a_j = \lambda_j a_j$ and P an orthogonal projection such that $P^* A_n P = A_{n-1}$ we have

$$\begin{aligned} \lambda_i(A_{n-1}) &= \sup_{v \in S_i, \|v\|=1} v^* A_{n-1} v = \\ &= \sup_{v \in S_i, \|v\|=1} v^* P^* A_n P v \geq \\ &= \inf_{\dim(V)=n-i} \sup_{v \in V, \|v\|=1} v^* A_n v = \lambda_{i+1}(A_n), \end{aligned}$$

and

$$\begin{aligned} \lambda_i(A_n) &= \inf_{\dim(V)=n-i+1} \sup_{v \in V, \|v\|=1} v^* A_n v \geq \\ &= \sup_{v \in S_i, \|v\|=1} v^* P^* A_n P v = \\ &= \sup_{v \in S_i, \|v\|=1} v^* A_{n-1} v = \lambda_i(A_{n-1}). \end{aligned}$$

\square

Remembering the identity $Im(s_{\mu_n(a+ib)}) = \pi\mu * P_b(a)$ and that $supp\mu_n$ consists of finitely many points, we have $Im(s_{\mu_n}) = \pi\frac{1}{n} \sum_i \frac{b}{(\lambda_i - a)^2 + b^2}$ which suggests that it is important to take a closer look at the function $x \mapsto \frac{b}{(x-a)^2 + b^2}$ to compare s_{μ_n} with $s_{\mu_{n-1}}$.

Lemma 0.5.10. *For fixed $z \in \mathbb{C}_+$ the Stieltjes transform is “stable” in n , i.e.*

$$s_n(z) = s_{n-1}(z) + O\left(\frac{1}{n}\right)$$

Proof. The idea is to use the Cauchy interlacing theorem and apply it to the previously mentioned identity by seeing that

$$\sum_{j=1}^{n-1} \frac{b}{\lambda_j(M_{n-1})/\sqrt{n} - a} - \sum_{j=1}^n \frac{b}{\lambda_j(M_n)/\sqrt{n} - a} \quad (7)$$

is an alternating sum of evaluations of $x \mapsto \frac{b}{(x-a)^2 + b^2}$. Since this function is bounded uniformly in n (7) is bounded uniformly in n . Up to the dimensional factors these two sums correspond to s_n and s_{n-1} , giving

$$\sqrt{n(n-1)}s_{n-1}(\sqrt{n/(n-1)}(a+ib)) - ns_n(a+ib) = O(1).$$

Now using the fact that the Stieltjes transform s_n is analytic away from the support of μ_n (0.5.7.2) and using the bound for its derivatives (0.5.7.3) we can approximate $s_{n-1}(\cdot)$ by $s_{n-1}(\sqrt{n/(n-1)} \cdot)$ and hence the statement holds. \square

Using McDiarmid’s inequality one gets

$$\mathbb{P}(|s_n(z) - \mathbb{E}s_n(z)| \geq \lambda/\sqrt{n}) \leq C \exp^{-c\lambda^2}, \quad (8)$$

for all $\lambda > 0$ and some constants $c, C > 0$.

From the Borel-Cantelli lemma we see that for every z away from the real line $s_n(z) - \mathbb{E}s_n(z)$ converges almost surely to zero since, for every fixed $\varepsilon > 0$, the sum $\sum_n \mathbb{P}(d(s_n - \mathbb{E}s_n, 0) \geq \varepsilon) \leq C \sum_n \exp^{-cn\varepsilon^2} < \infty$ which is obtained by setting $\lambda = \varepsilon\sqrt{n}$.

0.5.4 Finding the Semicircle Law

We start off by noting the following identity

$$s_n(z) := \int_{\mathbb{R}} \frac{1}{x-z} d\mu_n(x) = \frac{1}{n} \text{tr} \left(\frac{1}{\sqrt{n}} M_n - zI_n \right)^{-1},$$

which holds for every $z \in \mathbb{C} \setminus \text{supp}(\mu_n)$. Because of the linearity of the trace we also have

$$\mathbb{E}s_n(z) = \frac{1}{n} \sum_{j=1}^n \mathbb{E} \left[\left(\frac{1}{\sqrt{n}} M_n - z I_n \right)^{-1} \right]_{jj} = \mathbb{E} \left[\left(\frac{1}{\sqrt{n}} M_n - z I_n \right)^{-1} \right]_{nn}, \quad (9)$$

where the last equality holds because all of the random variables $[(M_n/\sqrt{n} - z I_n)^{-1}]_{jj}$ have the same distribution.

To calculate one entry of an inverse of a matrix we use Schur's complement formula, which tells us that (under the assumption that all the occurring inverse matrices exist)

$$[(M_n/\sqrt{n} - z I_n)^{-1}]_{nn} = - \left(z + \frac{1}{n} X^* \left(\frac{1}{\sqrt{n}} M_{n-1} - z I_{n-1} \right)^{-1} X \right)^{-1},$$

where $X \in \mathbb{C}^{n-1}$ is the top right column of M_n with the bottom entry removed and the diagonal elements have been set to zero as justified in 0.5.1.

Remark. *This inverse exists because, for $z \in \mathbb{C}_+$, the imaginary part $Q := \text{Im} \left(\left(\frac{1}{\sqrt{n}} M_{n-1} - z I_{n-1} \right)^{-1} \right)$ is positive definite according to the spectral theorem. To see this notice that this holds for arbitrary Hermitian matrices M (instead of $\frac{1}{\sqrt{n}} M_{n-1}$) since their spectrum is on the real line. Thus, by the spectral theorem, we can write $Q = \text{Im} \int \frac{1}{\mu_M - z} dM(\mu_M)$ for some projection valued measure dM and since $x \mapsto \frac{1}{x-z}$ is a Herglotz function its imaginary part will be greater than zero for $z \in \mathbb{C}_+$. As a result the imaginary part of the integrand (which is the imaginary part of the eigenvalues) will be greater than zero. We conclude by noticing that $\text{Im}(z) > 0$ plus something of the form $\langle Qx, x \rangle$ for $Q \geq 0$ will have imaginary part strictly greater than zero and hence the inverse exists.*

The next step is to get a better understanding of the resolvent $R := \left(\frac{1}{\sqrt{n}} M_{n-1} - z I_{n-1} \right)^{-1}$ and its product $\langle RX, X \rangle$. Clearly R and X are independent, so we may treat R almost like a deterministic matrix. Furthermore, again due to the spectral theorem, $\|R\|_{op}$ is at most $O(1)$. It can be seen that $\|X\| = O(\sqrt{n})$ almost surely and by Chernoff's inequality this holds with overwhelming probability.

In the following we will show some results for some deterministic matrix A which has roughly the same properties as R (i.e. $A \geq 0$ and $\|A\|_{OP} = O(1)$).

Noting that the function $X \mapsto \sqrt{\langle AX, X \rangle}$ is Lipschitz with operator norm $O(1)$ and remembering from 0.5.1 that we can safely assume the entries to be bounded, we can invoke Talagrand's concentration inequality to get

$$\mathbb{P}(|\sqrt{\langle AX, X \rangle} - \mathbb{M}\sqrt{\langle AX, X \rangle}| \geq \lambda) \leq C \exp^{-c\lambda^2}$$

for any $\lambda > 0$. On the other hand we have $\sqrt{\langle AX, X \rangle} = O(\|X\|) = O(\sqrt{n})$ with overwhelming probability (since the operator norm in the non-deterministic case is only controlled with overwhelming probability). Hence the median $\mathbb{M}\sqrt{\langle AX, X \rangle} = O(\sqrt{n})$ and considering the square $\langle AX, X \rangle$, we conclude that

$$\mathbb{P}(|\langle AX, X \rangle - \mathbb{M}\langle AX, X \rangle| \geq \lambda\sqrt{n}) \leq C \exp^{-c\lambda^2}$$

with some (possibly different) $c, C > 0$, since taking the square of $\sqrt{\langle AX, X \rangle}$ amounts to getting an additional factor $O(\sqrt{n})$ and the median is of the same magnitude as the random variable.

Because of this concentration of measure result we may replace the median with the expected value, yielding

$$\mathbb{P}(|\langle AX, X \rangle - \mathbb{E}\langle AX, X \rangle| \geq \lambda\sqrt{n}) \leq C \exp^{-c\lambda^2} \quad (10)$$

for the the case where A is deterministic and positive definite. One can extend this result to arbitrary matrices of operator norm $O(1)$ by noting that it holds for Hermitian $M = M^* = M_+ - M_-$ ($M_+ \geq 0, M_- \geq 0$) and general matrices $M = \tilde{M} + i\hat{M}$ (\tilde{M}, \hat{M} Hermitian) of operator norm $\|M\|_{op} = O(1)$ by applying the triangle inequality.

Remark. By using conditional expectations the above results also hold true for random matrices R with $R \geq 0$ and $\|R\|_{OP} = O(1)$ as long as it is independent of X . The idea is to write all the above statements as $\mathbb{P}(E|\{A = R\}) = \frac{\mathbb{P}(E \cap \{A=R\})}{\mathbb{P}(\{A=R\})} = \mathbb{P}(E)$ for all events E independent of R .

Now we want to know what $\mathbb{E}\langle RX, X \rangle$ actually is. Because of the linearity of the expectation we write it as $\sum_{i,j=1}^{n-1} \mathbb{E}[\overline{X_i} R_{ij} X_j]$. Since the X_i and R_{ij} are independent we can write that as $\sum_{i,j=1}^{n-1} \mathbb{E}[\overline{X_i} X_j] \mathbb{E}[R_{ij}]$, but as the X_i are iid with mean zero and variance one this double sum simplifies to the expectation of the trace of R

$$\sum_{i,j=1}^{n-1} \mathbb{E}[\overline{X_i} X_j] \mathbb{E}[R_{ij}] = \sum_{i=1}^{n-1} \mathbb{E} R_{ii}.$$

Noticing that, up to some “almost correct” normalization factors, $tr(R) = tr((M_{n-1}/\sqrt{n} - zI_{n-1})^{-1})$ is the Stieltjes transform $s_{n-1}(z)$. To be more precise we have

$$tr(R) = n\sqrt{\frac{n}{n-1}}s_{n-1}\left(\sqrt{\frac{n}{n-1}}z\right),$$

but because of the smoothness of the Stieltjes transform for $z \in \mathbb{C}_+$ these factors do not play a role in the limit $n \rightarrow \infty$, i.e. $tr(R) = n(s_{n-1}(z) + o(1))$.

So using the concentration of measure results for the Stieltjes transform ((8)) and for $\langle AX, X \rangle$ ((10)), remembering that latter also holds for random matrices as long as they are independent (0.5.4), we see that

$$\langle RX, X \rangle = n(s_{n-1}(z) + o(1))$$

with overwhelming probability. Substituting back in Schur’s complement ((9)) we get⁸

$$\mathbb{E}s_n(z) = -(z + \mathbb{E}s_n(z))^{-1} + o(1).$$

To say something about the limit we first need to ensure $\lim_{n \rightarrow \infty} \mathbb{E}s_n$ exists. This is indeed the case since $\mathbb{E}s_n$ is locally equicontinuous and locally uniformly bounded away from the real line. Applying the Arzelá-Ascoli theorem we get the existence of a subsequence that converges locally uniformly to a limit s , which is again a Herglotz function. Note that, by the concentration of measure for Stieltjes transforms, there is only one possible limit (so $\lim_{n \rightarrow \infty} \mathbb{E}s_n$ is well defined) and $s_n(z)$ even converges almost surely to $s(z)$. As a further result we get

$$s(z) = -(z + s(z))^{-1},$$

where the quadratic formula gives

$$s(z) = -\frac{z \pm \sqrt{z^2 - 4}}{2}.$$

From $\lim_{a \rightarrow \infty} s_\mu(a + ib) = 0$ for every Stieltjes transform of a fixed measure μ we see that we need to take $s(z) = \frac{-z + \sqrt{z^2 - 4}}{2}$.

We conclude the proof with the Stieltjes inversion formula, yielding the famous result

⁸Note that we need the concentration of measure results from above to justify “interchanging” expectation and taking the resolvent!

$$\frac{s(\cdot + ib) - s(\cdot - ib)}{2\pi i} \rightarrow \frac{1}{2\pi} \sqrt{4 - x^2}_+ dx = \mu_{sc}$$

as $b \rightarrow 0^+$, which can be verified by an application of the Cauchy integral formula.

0.6 Gaussian Random Fields

It turns out that our (random) Hamiltonian of interest $H_{N,p}$ belongs to a much more general class of random variables, namely Gaussian random fields. In order to simplify expressions like the expected number of critical points we need to know about covariance structures of Gaussian random fields and their derivatives, as well as how they behave under conditioning.

Definition 0.5 (Real valued random fields). *Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space and T a topological space. Then a measurable mapping $f : \Omega \rightarrow \mathbb{R}^T$ is called a real valued random field.*

In other words, a (real) random field f can be seen as a function $T \rightarrow \mathbb{R}$ where every $f(t)$ is a real valued random variable.

Definition 0.6 (Real valued Gaussian fields). *Let f be a real valued random field with some parameter set T as before. Then f is a real valued Gaussian field if for every $(t_1, \dots, t_n) \in T^n$ ($1 \leq n < \infty$) the distributions of the n -tuple $(f(t_1), \dots, f(t_n))$ are multivariate Gaussian.*

Furthermore the functions $m(t) = \mathbb{E}[f(t)]$ and $C(t, t') = \mathbb{E}[(f(t) - m(t))(f(t') - m(t'))]$ are called the mean and covariance functions of f , respectively.

Note that this definitions yields the usual definition for a multivariate Gaussian \mathbb{R}^d -valued random variable in case $|T| = d$ is finite.

The formulation and proofs of the following two lemmata will closely follow Auffinger et al. (2013) (and Adler and Taylor (2007) for the proofs). For what follows we shall fix some notations like in Auffinger et al. (2013): First of all, instead of working with $H_{N,p}$ it is convenient to define

$$f(\sigma) \equiv f_{N,p}(\sigma) = N^{-1/2} H_{N,p}(N^{1/2}\sigma), \quad (11)$$

which has variance one on the unit sphere. We use $\langle \cdot, \cdot \rangle$ to denote the usual Euclidean scalar product, as well as the scalar product on any tangent space $T_\sigma S^{N-1}$ and $(E_i)_{1 \leq i < N}$ to denote an arbitrary orthonormal frame field, that is a set of $N - 1$ vector fields E_i on S^{N-1} such that $\{E_i(\sigma)\}$ is

an orthonormal basis of $T_\sigma S^{N-1}$ for all $\sigma \in S^{N-1}$. Furthermore we write $\nabla f(\sigma) = (f_i(\sigma))_{1 \leq i < N}$ for the gradient $(E_i f(\sigma))_{1 \leq i < N}$, $\nabla^2 f = (f_{ij})_{1 \leq i, j < N}$ for the covariant Hessian of f on S^{N-1} and $\det \nabla^2 f(\sigma)$ for the determinant of the matrix $(\nabla^2 f(E_i, E_j)(\sigma))_{1 \leq i, j < N}$.

At this point it should be noted that, a priori, it is not obvious that derivatives such as ∇f or $\nabla^2 f$ exist and if so in which sense. We will quickly sketch the existence in the L^2 sense and skip the question of being almost surely continuously differentiable. To that end let us define the symmetrized difference

$$F(t, t') = \frac{1}{\prod_{i=1}^k |t'_i|} \sum_{s \in \{0,1\}^k} (-1)^{k - \sum_{i=1}^k s_i} f\left(t + \sum_{i=1}^k s_i t'_i\right),$$

which is related to the k -th L^2 derivative $D_{L^2}^k f(t, t')$ in direction t' at point t by

$$D_{L^2}^k f(t, t') = \lim_{h \rightarrow 0} F(t, ht').$$

Now a sufficient condition for L^2 differentiability of order k is that the limit

$$\lim_{|t|, |t'| \rightarrow 0} \mathbb{E}[F(s, t)F(s, t')]$$

exists, since a sequence X_n of random variables converges in L^2 if and only if $\mathbb{E}[X_n X_m]$ converges to a constant as $n, m \rightarrow \infty$ which can be seen (e.g. for the first derivative) by multiplying out the terms in

$$\lim_{h, h' \rightarrow 0} \mathbb{E} \left[\frac{f(s + ht) - f(s)}{h} \frac{f(s + h't) - f(s)}{h'} \right],$$

using the linearity of the expectation, as well as the covariance structure $(\mathbb{E}[f(x)f(y)] = C(x, y) = \langle x, y \rangle^p)$ and Taylor expanding (dropping terms of the form $\frac{1}{hh'} O(h^{1+i} h'^{1+j})$ for $i + j > 0$ that vanish in the limit) resulting in some finite number, possibly depending on p , but independent on h, h' .

Lemma 0.6.1 (Covariances of f). *Let f be as defined in 11, then $f(\sigma)$, $f_i(\sigma)$, $f_{ij}(\sigma)$ are centered Gaussian random variables for all $1 \leq i, j, k, l < N$ and $\sigma \in S^{N-1}$ whose joint distribution is determined by*

$$\begin{aligned} \mathbb{E}[f(\sigma)^2] &= 1, \\ \mathbb{E}[f(\sigma)f_i(\sigma)] &= \mathbb{E}[f_i(\sigma)f_{jk}(\sigma)] = 0, \\ \mathbb{E}[f_i(\sigma)f_j(\sigma)] &= -\mathbb{E}[f(\sigma)f_{ij}(\sigma)] = p\delta_{ij}, \\ \mathbb{E}[f_{ij}(\sigma)f_{kl}(\sigma)] &= p(p-1)(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}) + p^2\delta_{ij}\delta_{kl}. \end{aligned} \quad (12)$$

Proof. Because of the rotational symmetry we may assume without loss of generality that σ is the north pole $n = (0, \dots, 0, 1)$. We define the projection $\Psi : S^{N-1} \rightarrow \mathbb{R}^{N-1}, (x_1, \dots, x_{N-1}, x_N) \mapsto (x_1, \dots, x_{N-1})$ which is a chart for some neighbourhood U of n and set $\bar{f} = f \circ \Psi^{-1}$ which is a Gaussian process on $\Psi(U)$, satisfying

$$C(x, y) = \text{Cov}(\bar{f}(x), \bar{f}(y)) = \left(\sum_{i=1}^{N-1} x_i y_i + \sqrt{(1 - \sum_{i=1}^{N-1} x_i^2)(1 - \sum_{i=1}^{N-1} y_i^2)} \right)^p.$$

Choosing an orthonormal frame field (E_i) such that it satisfies $E_i(n) = \partial/\partial x_i$ with respect to the chart Ψ the Christoffel symbols vanish and hence the covariant Hessian $(f_{ij}(n))$ agrees with the usual Hessian of \bar{f} at 0.

Thus it suffices to prove the analogous identities for $\bar{f}(0)$, $\frac{\partial}{\partial x_i} \bar{f}(0)$ and $\frac{\partial^2}{\partial x_i \partial x_j} \bar{f}(0)$.

To do so we first want to show

$$\mathbb{E} \left\{ \frac{\partial^k \bar{f}(s)}{\partial s_{i_1} \dots \partial s_{i_k}} \frac{\partial^l \bar{f}(t)}{\partial t_{i_1} \dots \partial t_{i_l}} \right\} = \frac{\partial^{k+l} C(s, t)}{\partial s_{i_1} \dots \partial s_{i_k} \partial t_{i_1} \dots \partial t_{i_l}}, \quad (13)$$

which, in turn, after some simple algebra gives (12).

For the sake of clarity let us show the special case $\mathbb{E}[f_i(s)f_j(t)] = \frac{\partial^2 C(s, t)}{\partial s_i \partial t_j}$; the result for higher orders follows analogously. We have that

$$\mathbb{E}[f_i(s)f_j(t)] = \int \lim_{h \rightarrow 0} \frac{f(\omega)(s + he_i) - f(\omega)(s)}{h} \frac{f(\omega)(t + he_j) - f(\omega)(t)}{h} \phi(\omega) d\omega,$$

for some Gaussian density ϕ . Note that $f(\cdot)(s)$ (as a sum of Gaussians) is Gaussian and almost surely continuously differentiable⁹; hence the integrand, as a product of difference quotients times some probability density ϕ , is uniformly (in h) bounded by $f_i(\cdot)(s)f_j(\cdot)(t)\phi(\cdot)$ which is integrable. As a result we can apply the dominated convergence theorem which gives us the following equality

$$\begin{aligned} \mathbb{E}[f_i(s)f_j(t)] &= \\ \lim_{h \rightarrow 0} \int \frac{(f(\omega)(s + he_i) - f(\omega)(s))(f(\omega)(t + he_j) - f(\omega)(t))}{h^2} \phi(\omega) d\omega. \end{aligned}$$

Multiplying it out and using the linearity of the integral yields this special case of (13). □

⁹We didn't show that, but conditions for almost sure continuous differentiability can be found (and checked) in Adler and Taylor (2007).

Now we can formulate one of the central identities that allow us to use methods from random matrix theory to study the Hamiltonian of interest.

Lemma 0.6.2 (Moments under conditioning). *Using the same assumptions as in the previous lemma and under the conditional distribution $\mathbb{P}[\cdot|f(\sigma) = x]$, $x \in \mathbb{R}$ the random variables $f_{ij}(\sigma)$ are independent Gaussian variables satisfying*

$$\begin{aligned}\mathbb{E}[f_{ij}(\sigma)|f(\sigma) = x] &= -xp\delta_{ij}, \\ \mathbb{E}[f_{ij}(\sigma)^2|f(\sigma) = x] &= (1 + \delta_{ij})p(p-1).\end{aligned}\tag{14}$$

Alternatively, the random matrix $(f_{ij}(\sigma))$ (under the conditional distribution $\mathbb{P}[\cdot|f(\sigma) = x]$, $x \in \mathbb{R}$) has the same distribution as

$$M^{N-1}\sqrt{2(N-1)p(p-1)} - xpI,$$

where M^{N-1} is a $(N-1) \times (N-1)$ GOE matrix as defined in 0.1 and I is the identity matrix.

Proof. Equations (14) can be seen from the last two equations of (12) and by using the identity $\mathbb{E}[Y|X = x] = \mathbb{E}[Y] + \Sigma_{YX}\Sigma_{XX}^{-1}(x - \mathbb{E}[X])$ which holds for $(X, Y) \in \mathbb{R}^n$ normally distributed with covariance matrix $\Sigma = (\Sigma_{ij})_{i,j=1}^n$, and setting X to be $f(\sigma)$ and Y to be $f_{ij}(\sigma)$.

The second statement follows by plugging in the definitions. \square

0.7 Large Deviation Principles

So-called “large deviation principles” will allow us to study the asymptotic decay of probabilities \mathbb{P}_n as some parameter n goes to infinity in a systematic manner.

Definition 0.7 (Large deviation principle). *Given some separable completely metrizable topological space X , a sequence of Borel probability measures $\{\mathbb{P}_n\}$ on X is said to satisfy a **large deviation principle** with speed $\{a_n\}$ and rate $I : X \rightarrow [0, \infty]$ if a_n goes to $+\infty$ and I is a lower semi-continuous functional such that for each Borel measurable set $E \subseteq X$ we have*

$$\limsup_n a_n^{-1} \log(\mathbb{P}_n(E)) \leq - \inf_{x \in E} I(x)$$

and

$$\liminf_n a_n^{-1} \log(\mathbb{P}_n(E)) \geq - \inf_{x \in E^\circ} I(x).$$

The lower semi-continuity implies that the sets $\{x \in X : I(x) \leq c\}$ are closed in X for all $c \geq 0$. If they are also compact for all $c \geq 0$, I is called a **good rate function**.

We are particularly interested in getting LDPs of the k -th largest eigenvalues of the GOE, but it turns out in order to get those we first need a LDP for the law of the empirical measure $\mu^N = \frac{1}{N} \sum_{i=1}^N \delta_{\lambda_i}$.

Theorem 0.7.1 (LDP of Wigner's semicircle law for the GOE). *Let $I(\mu) := \frac{1}{2} (\int x^2 d\mu(x) - \Sigma(\mu) - \frac{3}{4} - \frac{1}{2} \log 2)$, for $\Sigma(\mu) := \int \int \log |x - y| d\mu(x) d\mu(y)$. Then I is well defined on the space of probability measures $\mathcal{M}(\mathbb{R})$ on \mathbb{R} endowed with the weak topology and takes values in $[0, \infty]$. In particular the law of the empirical measure μ^N satisfies a LDP with good rate function I and speed N^2 .*

A proof can be found in Ben Arous and Guionnet (1997).

With this we can state the most important theorem of this section.

Theorem 0.7.2 (LDP for the k -th largest eigenvalue of the GOE). *For each fixed $k \geq 1$, the k -th largest eigenvalue λ_{N-k+1} of the GOE satisfies a LDP with speed N and good rate function*

$$I_k(x) = kI_1(x) = \begin{cases} k \int_2^x \sqrt{\frac{z^2}{4} - 1} dz, & \text{if } x \geq 2 \\ \infty, & \text{else.} \end{cases}$$

Another result that will be used later on is Varadhan's lemma which can be viewed as the LDP equivalent of Laplace's principle which states that $\lim_{\varepsilon \rightarrow 0} \varepsilon \int_A \exp(-\phi(x)/\varepsilon) dx = -\inf_{x \in A} \phi(x)$ or more loosely $\int_A \exp(-\phi(x)/\varepsilon) dx \approx \exp(-\inf_{x \in A} \phi(x)/\varepsilon)$.

Lemma 0.7.3 (Varadhan). *Let X_ε be random variables in a metric space M that satisfy a LDP with rate $1/\varepsilon$ and rate function J , and $\phi : M \rightarrow \mathbb{R}$ be continuous and bounded from above. Then*

$$\lim_{\varepsilon \rightarrow 0} \varepsilon \log \mathbb{E}[\exp(\phi(X_\varepsilon)/\varepsilon)] = \sup_{x \in M} \phi(x) - J(x).$$

Proof. This proof follows Shalizi (2006). We will show that \limsup and \liminf are both equal to $\sup_x \phi(x) - J(x)$ and start with the \limsup : To that end pick an arbitrary positive n . Since ϕ is continuous and bounded from above, there exists a finite family of closed sets $\{B_i\}_{i=1}^{m_n}$, such that

$\phi(x) \leq -n$ on the complement of their union and that within each B_i we have that ϕ varies only by at most $1/n$. Using those definitions we get

$$\begin{aligned}
\limsup \varepsilon \log \mathbb{E}[\exp(\phi(X_\varepsilon)/\varepsilon)] &\leq (-n) \vee \max_{i=1}^m \limsup \varepsilon \log \mathbb{E}[\exp(\phi(X_\varepsilon)/\varepsilon) \mathbf{1}\{X_\varepsilon \in B_i\}] \\
&\leq (-n) \vee \max_{i=1}^m \sup_{x \in B_i} \phi(x) - \inf_{x \in B_i} J(x) \\
&\leq (-n) \vee \max_{i=1}^m \sup_{x \in B_i} \phi(x) - J(x) + 1/n \\
&\leq (-n) \vee \sup_{x \in M} \phi(x) - J(x) + 1/n.
\end{aligned}$$

Letting $n \rightarrow \infty$ we get $\limsup \varepsilon \log \mathbb{E}[\phi(X_\varepsilon)/\varepsilon] = \sup \phi(x) - J(x)$. To get the \liminf , pick any $x \in M$ and let $B_\delta(x)$ be a ball of arbitrary radius δ centered at x . We have

$$\begin{aligned}
\liminf \varepsilon \log \mathbb{E}[\phi(X_\varepsilon)/\varepsilon] &\geq \liminf \varepsilon \log \mathbb{E}[\phi(X_\varepsilon)/\varepsilon \mathbf{1}\{X_\varepsilon \in B_\delta(x)\}] \\
&\geq \inf_{y \in B_\delta(x)} \phi(x) - \inf_{y \in B_\delta(x)} J(x) \\
&\geq \inf_{y \in B_\delta(x)} \phi(x) - J(x).
\end{aligned}$$

Since δ was arbitrary we can let it go to zero, yielding $\inf_{y \in B_\delta(x)} \phi(x) = \phi(x)$ by continuity of ϕ . This holds for arbitrary x so we can take the supremum over x which proves the claim. \square

0.8 Kac-Rice formula

To count zeros of a “sufficiently well-behaved” function $f : I \rightarrow \mathbb{R}$ one could try to write it an integral over the values $x : |f(x)| < \varepsilon$; however, one has to be careful about the scaling properties: While the number of zeros is invariant under linear scaling an integral clearly is not. To that end we define a kernel $\varphi_\varepsilon : \mathbb{R} \rightarrow \mathbb{R}$, such that

$$\varphi_\varepsilon(x) = \begin{cases} \frac{1}{2\varepsilon}, & \text{if } |x| < \varepsilon \\ 0, & \text{else.} \end{cases}$$

Clearly $\lim_{\varepsilon \rightarrow 0} \int_{\mathbb{R}} \varphi_\varepsilon(x) f(x) = f(0)$ and

$$\int_I \varphi_\varepsilon(f(x)) |f'(x)| dx = \frac{1}{2\varepsilon} \int_{x: |f(x)| < \varepsilon} |f'(x)| dx, \quad (15)$$

for ε small enough. Now let $x_0 \in f^{-1}(0)$, $x_+ = \min\{x > x_0 : |f(x)| = \varepsilon\}$ and $x_- = \max\{x < x_0 : |f(x)| = \varepsilon\}$, to get

$$\int_{x_-}^{x_+} |f'(x)| dx = |f(x_+) - f(x_-)| = 2\varepsilon,$$

which motivates using (15) to count zeros of a function f which satisfies the following definition:

Definition 0.8 (Convenient functions). *A C^1 function $f : [a, b] \rightarrow \mathbb{R}$ is called convenient if $f(a), f(b) \neq 0$ and all zeros are nondegenerate, i.e. $f(x) = 0 \implies f'(x) \neq 0$.*

To generalize this intuition to higher dimensions it is useful to think of the derivative factor as some kind of normalisation of the “volume” around the root (f has the same number of zeros as cf for $c \in \mathbb{R} \setminus \{0\}$). Thus, if we want to count critical points (i.e. substitute f by ∇f and f' by $\nabla^2 f$ in the above considerations), it is natural to take the determinant of the Hessian $\nabla^2 f$. Indeed this turns out to be true; however, going back to our rescaled Hamiltonian f , as defined in 0.6 we claim that

$$\mathbb{E}Crt_N^f(B) = \int_{S^{N-1}} \mathbb{E}[|\det \nabla^2 f(\sigma)| \mathbf{1}\{f(\sigma) \in B\} |\nabla f(\sigma) = 0|] d\mathbb{P}(\nabla f(\sigma) = 0) d\sigma. \quad (16)$$

While the above considerations motivate the choice of this integrand, it still remains to be checked what kind of criteria we have to impose on a random f for this formula to hold. We will formulate these conditions in the following lemma:

Theorem 0.8.1 (Kac-Rice formula for centered Gaussian fields). *Let f be a centered Gaussian field on S^{N-1} and let $\mathcal{A} = (U_\alpha, \Psi_\alpha)_{\alpha \in I}$ be a finite atlas on S^{N-1} . Set $f^\alpha = f \circ \Psi_\alpha^{-1}$ and denote the derivatives analogously to 0.6. Assume that for all $\alpha \in I$ and all $x, y \in \Psi_\alpha(U_\alpha)$ the joint distribution of $(f_i^\alpha(x), f_{ij}^\alpha(x))_{1 \leq i, j < N}$ is nondegenerate, and*

$$\max_{i,j} |Var(f_{ij}^\alpha(x) + Var(f_{ij}^\alpha(y) - 2Cov(f_{ij}^\alpha(x), f_{ij}^\alpha(y)))| \leq K_\alpha |\log |x - y||^{-1-\beta}$$

for some $K_\alpha, \beta > 0$. Then equation (16) holds.

A proof can be found in Adler and Taylor (2007).

0.9 Landscapes of Spherical Spin Glasses

To prove our main results (0.2.1 and 0.2.2) we first need some refinements for the expected number of critical values.

Theorem 0.9.1 (Express $\mathbb{E}[Crt_{N,k}(B)]$ in terms of the GOE). *For all Borel sets B , natural numbers $N, p \geq 2$ and $k \in \{0, \dots, N-1\}$ we have*

$$\mathbb{E}[Crt_{N,k}(B)] = 2\sqrt{\frac{2}{p}}(p-1)^{\frac{N}{2}} \mathbb{E}_{GOE}^N \left[e^{-N\frac{p-2}{2p}(\lambda_k^N)^2} \mathbf{1} \left\{ \lambda_k^N \in \sqrt{\frac{p}{2(p-1)}}B \right\} \right] \quad (17)$$

and

$$\mathbb{E}[Crt_N(B)] = 2N\sqrt{\frac{2}{p}}(p-1)^{\frac{N}{2}} \int_{\sqrt{\frac{p}{2(p-1)}}B} \exp \left\{ -\frac{N(p-2)x^2}{2p} \right\} \rho_N(x) dx. \quad (18)$$

Proof. First of all let us show that we can apply lemma 0.8.1. To do so we use the same notation as in section 0.6. Because of the rotational symmetry and since S^{N-1} can be covered by a finite number of copies of an open neighbourhood of some point it suffices to investigate only one point. We will choose the north-pole n and see that $(f_i(n), f_{ij}(n))$ is not degenerate. Since the covariances are continuous this is also true for some neighbourhood U . Hence the conditions of lemma 0.8.1 are satisfied. Again due to the rotational symmetry the integrand does not depend on σ , so we get

$$\mathbb{E}Crt_{N,k}(B) = \text{vol}(S^{N-1}) \mathbb{E}[|\det \nabla^2 f(n)| \mathbf{1}\{i(\nabla^2 f(n)) = k, f(n) \in \sqrt{N}B\} | \nabla f(n) = 0] d\mathbb{P}(\nabla f(n) = 0)$$

To compute this expectation we condition on $f(n)$:

$$\begin{aligned} & \mathbb{E}[|\det \nabla^2 f(n)| \mathbf{1}\{i(\nabla^2 f(n)) = k, f(n) \in \sqrt{N}B\} | \nabla f(n) = 0] = \\ & \mathbb{E} \left[\mathbb{E}[|\det \nabla^2 f(n)| \mathbf{1}\{i(\nabla^2 f(n)) = k, f(n) \in \sqrt{N}B\} | f(n)] \right] \end{aligned}$$

By lemma 0.6.1 we get the following equality for the interior expectation

$$\begin{aligned} & \mathbb{E}[|\det \nabla^2 f(n)| \mathbf{1}\{i(\nabla^2 f(n)) = k, f(n) \in \sqrt{N}B\} | f(n)] = \\ & (2(N-1)p(p-1))^{(N-1)/2} \mathbb{E}_{GOE}^{N-1} \left[|\det(M^{N-1} - \sqrt{p/(2(N-1)(p-1))}f(n)I)| \right. \\ & \left. \times \mathbf{1}\{i(M^{N-1} - \sqrt{p/(2(N-1)(p-1))}f(n)I) = k, f(n) \in \sqrt{N}B\} \right]. \end{aligned}$$

Substituting back, writing t^2 for $p/(2(N-1)(p-1))$ as well as G for $\sqrt{Np/(2(N-1)(p-1))}B$ and setting X to be a real valued Gaussian random variable with zero mean and variance t^2 we get

$$\begin{aligned} \mathbb{E} \left[|\det(M^{N-1} - XI) \mathbf{1}\{i(M^{N-1} - XI) = k, X \in G\}| \right] = \\ (2\pi t^2)^{-1/2} \int_G \exp\left(-\frac{x^2}{2t^2}\right) \mathbb{E}_{GOE}^{N-1} \left[|\det(M - xI) \mathbf{1}\{i(M - xI) = k\}| \right] dx. \end{aligned} \quad (19)$$

Now observe that the event $\{i(M - xI) = k\}$ is equal to the event $\{A_k^N(x)\}$, where $A_k^N(x) = \{\lambda^{N-1} : \lambda_0^{N-1} \leq \dots \leq \lambda_{k-1}^{N-1} < x \leq \lambda_k^{N-1} \leq \dots \leq \lambda_{N-2}^{N-1}\}$.

Using theorem 0.4.1 we get

$$\mathbb{E}_{GOE}^{N-1} [|\det(M - xI) \mathbf{1}\{i(M - xI) = k\}|] = \int_{A_k^N(x)} \prod_{i=1}^{N-2} |\lambda_i^{N-1} - x| Q_{N-1}(d\lambda^{N-1}).$$

The definition of $A_k^N(x)$ and the determinant in the equation above suggests considering x as the $k+1$ -th smallest eigenvalue of a $N \times N$ GOE matrix. Performing the corresponding rescaling, that is, change of variables given by $\lambda_i^{N-1} = \sqrt{N/(N-1)}\lambda_i^N$ for $i \in \{0, \dots, k-1\}$, $\lambda_i^{N-1} = \sqrt{N/(N-1)}\lambda_{i+1}^N$ for $i \in \{k, \dots, N-2\}$ and $x = \sqrt{N/(N-1)}\lambda_k^N$, writing out Q_N and substituting back in equation (19) we obtain

$$\begin{aligned} \frac{Z_N}{Z_{N-1}\sqrt{2\pi t^2}} (N/(N-1))^{(N+2)(N+1)/4} \\ \times \mathbb{E}_{GOE}^N \left[\exp\left(\frac{N(\lambda_k^N)^2}{2} - \frac{N}{N-1} \frac{(\lambda_k^N)^2}{2t^2}\right) \mathbf{1}\{\lambda_k^N \in \sqrt{(N-1)/N}G\} \right], \end{aligned}$$

where the constants Z_N is given by

$$\frac{1}{N!} (2\sqrt{2})^N N^{-N(N+1)/4} \prod_{i=1}^N \Gamma(1 + i/2)$$

which can be computed from Selberg's integral (cf. Mehta (2004)).

Some algebra then yields the first claim, the second one is obtained by summing over $k \in \{0, \dots, N-1\}$.

□

Now we are ready to give a sketch of the proof of theorem 0.2.1:

Proof. For simplicity's sake we fix B in $\mathbb{ECrt}_{N,k}(B)$ to be $(-\infty, u)$. The proof naturally extends to arbitrary Borel sets B .

To declutter notation we set $t = u\sqrt{\frac{p}{2(p-1)}}$, $\phi(x) = -\frac{p-2}{2p}x^2$ and $J_k(u) = (k+1)I_1(-u; 2^{-1/2})$, where the additional argument $2^{-1/2}$ indicates some normalisation factor that we get since we are not dealing with random variables with variance one in this setting.

Now by theorem 17,

$$\lim_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{ECrt}_{N,k}(u) = \frac{1}{2} \log(p-1) + \lim_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}_{GOE}^N[\exp(N\phi(\lambda_k^2)\mathbf{1}_{\lambda_k \leq t})].$$

Since ϕ is bounded from above we can apply Varadhan's lemma to obtain

$$\begin{aligned} \sup_{x \in (-\infty, t)} (\phi(x) - J_k(x)) &\leq \liminf_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}_{GOE}^N[\exp(N\phi(\lambda_k^2)\mathbf{1}_{\lambda_k < t})] \\ &\leq \limsup_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}_{GOE}^N[\exp(N\phi(\lambda_k^2)\mathbf{1}_{\lambda_k \leq t})] \leq \sup_{x \in (-\infty, t]} (\phi(x) - J_k(x)). \end{aligned}$$

For $t \leq -\sqrt{2}$ both suprema equal $\phi(t) - J_k(t)$ and if $t > -\sqrt{2}$ they equal $\phi(\sqrt{2})$. The claim essentially follows after appropriate rescaling of the rate function I_1 (cf. Auffinger et al. (2013)). \square

Applying Markov's inequality to (1) (as in Auffinger et al. (2013) proof of theorem 2.14) then yields (3).
